Introduction

The Federal interagency community has developed fifteen all-hazards planning scenarios (the National Planning Scenarios or Scenarios) for use in national, Federal, State, and local homeland security preparedness activities. The Scenarios are planning tools and are representative of the range of potential terrorist attacks and natural disasters and the related impacts that face our nation. The objective was to develop a minimum number of credible scenarios in order to establish the range of response requirements to facilitate preparedness planning.

Since these Scenarios were compiled to be the minimum number necessary to develop the range of response capabilities and resources, other hazards were inevitably omitted. Examples of other potentially high-impact events include nuclear power plant incidents\(^1\), industrial and transportation accidents, and frequently occurring natural disasters. Entities at all levels of government can use the National Planning Scenarios as a reference to help them identify the potential scope, magnitude, and complexity of potential major events. Entities are not precluded from developing their own scenarios to supplement the National Planning Scenarios.

These Scenarios reflect a rigorous analytical effort by Federal homeland security experts, with reviews by State and local homeland security representatives. However, it is recognized that refinement and revision over time will be necessary to ensure the Scenarios remain accurate, represent the evolving all-hazards threat picture, and embody the capabilities necessary to respond to domestic incidents.

How to Use the National Planning Scenarios:

Capabilities-Based Planning

In seeking to prepare the Nation for terrorist attacks, major disasters and other emergencies, it is impossible to maintain the highest level of preparedness for all possibilities all of the time. Given limited resources, managing the risk posed by major events is imperative. In an atmosphere of changing and evolving threat, it is vital to build flexible capabilities that will enable the Nation, as a whole, to prevent, respond to and recover from a range of major events.

To address this challenge, DHS employs a capabilities-based planning process which is a planning process that occurs under uncertainty in order to identify capabilities suitable for a wide range of challenges and circumstances, while working within an economic framework that necessitates prioritization and choice. As a first step in the capabilities-based planning process, the Scenarios, while not exhaustive, provide an illustration of the potential threats for which we

---

\(^1\) A severe incident at a nuclear power plant, whether or not it is terrorist-initiated, could result in a release of radioactive materials to the environment with adverse consequences to public health. Scenarios for such severe incidents have not been included in this scenario set because: (1) current Federal regulations from the Nuclear Regulatory Commission and the DHS Federal Emergency Management Agency (FEMA) mandate robust emergency planning and preparedness for each nuclear plant to include the full range of response organizations; and (2) scenarios for nuclear plants cannot be generically extrapolated to other types of facilities (e.g., chemical plants).
must be prepared. The Scenarios were designed to be broadly applicable; they generally do not specify a geographic location, and the impacts are meant to be scalable for a variety of population and geographic considerations.

**HSPD-8 Implementation**

The Scenarios will be used in the implementation of HSPD-8, “National Preparedness,” including the development of the National Preparedness Goal and the National Exercise Program. In helping to develop the National Preparedness Goal, the Scenarios provide the foundation for identifying the capabilities across all mission areas and the target levels of those capabilities needed for effective prevention, response and recovery to major events, such as those outlined in the Scenarios. Examination of the Scenarios leads to certain common functions that must be accomplished. The need for response organizations to move quickly and in a coordinated manner and the requirements to quickly treat mass casualties and to assist displaced residents are examples. This commonality implies flexible, adaptive, and robust capabilities to cope with diverse events and hazards.

In addition, the Scenarios will be used as the design basis for exercises in the National Exercise Program. As a common foundation for exercise development, the Scenarios reduce the possibility that agencies exercising the same basic type of event will exercise greatly different consequences which may lead to vastly different capability requirements and preparedness expectations. While not meant to be all-inclusive, the scenarios provide a basic set of common homeland security events and their related impacts that can be employed at the national level or by States and localities. Although certain areas have special concerns – for example, continuity of Government in Washington, DC; viability of financial markets in New York; and trade and commerce in other major cities – the Scenarios have been developed in a way that allows them to be adapted to local conditions. Agencies will not be limited to this set of Scenarios, and they will continue to be able to exercise scenarios that are not specifically included in the planning set. However, when exercising the basic events included in the Scenario set, the Scenarios provide a mutual starting point.

**General Considerations for the Scenarios:**

**Future Development of Prequels –**

The goal of the current Scenarios is to flesh out response capabilities and needs, not threat-based prevention activities. However, for the terrorist attack Scenarios, DHS is working with the Federal interagency community to develop detailed prequels to the scenarios, including information on the perpetrator, the “Universal Adversary”, to help further prevention related planning and preparedness efforts. The UA prequels will be included in future iterations of the Scenario set.

**Scenario Outline –**

Each scenario in the National Planning Scenarios: Executive Summaries follows the same general outline, which is as follows:

- Scenario General Description
- Planning Considerations
National Planning Scenarios: FOR OFFICIAL USE ONLY Version 20.2 DRAFT

Executive Summaries

- Geographical Considerations/Description
- Timeline/Event Dynamics
- Mission Areas Activated

- Key Implications

Intelligence Disclaimer –
While the scenarios developed generally reflect possible terrorist capabilities and known tradecraft, neither the Intelligence Community nor the law enforcement community is aware of any credible specific intelligence that indicates that such an attack is being planned, or that the agents or devices in question are in possession of any known terrorist group.

Relative Grouping of Scenarios –
Depending on the ultimate use, various schemes have been used in the past to rank scenarios based on probability, number of casualties, extent of property damage, economic impact, and social disruption. Because the Scenarios in this set were developed to test the full range of response capabilities and resources – and to assist Federal, State, and local governments as well as the private sector in preparedness – they have not been ranked.

Multiple Events –
As there is a possibility that multiple incidents will occur simultaneously or sequentially, organizations should always consider the need to respond to multiple incidents of the same type and multiple incidents of different types, at either the same or other geographic locations, in preparedness planning efforts. These incidents will invariably require the coordination and cooperation of homeland security response organizations across multiple regional, State, and local jurisdictions.
**Mission Areas:**
The following Mission Areas were used to assist in scoping the response requirements generated by the scenarios.

<table>
<thead>
<tr>
<th>Mission Area</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Prevention/Deterrence</strong></td>
<td>The ability to detect, prevent, preempt, and deter terrorist attacks and other man-made emergencies</td>
</tr>
<tr>
<td><strong>Infrastructure Protection</strong></td>
<td>The ability to protect critical infrastructure from all threats and hazards</td>
</tr>
<tr>
<td><strong>Preparedness</strong></td>
<td>The ability to plan, organize, equip, train, and exercise homeland security personnel to perform their assigned missions to nationally accepted standards – this mission area includes public education and awareness</td>
</tr>
<tr>
<td><strong>Emergency Assessment/Diagnosis</strong></td>
<td>The ability to achieve and maintain a common operating picture, including the ability to detect an incident, determine its impact, determine its likely evolution and course, classify the incident, and make government notifications</td>
</tr>
<tr>
<td><strong>Emergency Management/Response</strong></td>
<td>The ability to direct, control, and coordinate a response; manage resources; and provide emergency public information – this outcome includes direction and control through the Incident Command System (ICS), Multiagency Coordination Systems, and Public Information Systems</td>
</tr>
<tr>
<td><strong>Hazard Mitigation</strong></td>
<td>The ability to control, collect, and contain a hazard, lesson its effects, and conduct environmental monitoring – mitigation efforts may be implemented before, during, or after an incident</td>
</tr>
<tr>
<td><strong>Evacuation/Shelter</strong></td>
<td>The ability to provide initial warnings to the population at large and at risk; notify people to shelter-in-place or evacuate; provide evacuation and shelter support; and manage traffic flow and ingress and egress to and from the affected area</td>
</tr>
<tr>
<td><strong>Victim Care</strong></td>
<td>The ability to treat victims at the scene; transport patients; treat patients at a medical treatment facility; track patients handle, track, and secure human remains; provide tracking and security of patients’ possessions and evidence; and manage the worried well</td>
</tr>
<tr>
<td><strong>Investigation/Apprehension</strong></td>
<td>The ability to investigate the cause and source of the incident and identify, apprehend, and prosecute those responsible for terrorist attacks and other manmade emergencies</td>
</tr>
<tr>
<td><strong>Recovery/Remediation</strong></td>
<td>The ability to restore essential services, businesses, and commerce; cleanup the environment and render the affected area safe; compensate victims; provide long-term mental health and other services to victims and the public; and restore a sense of well-being in the community</td>

Scenario General Description:

In this scenario, terrorist members of the Universal Adversary (UA) group plan to assemble a gun-type nuclear device using highly enriched uranium (HEU) stolen from a nuclear facility in another country. The nuclear device components are smuggled into the United States, and the device is assembled near a major metropolitan center. Using a delivery van, terrorists plan to transport the device to the business district of a large city and detonate it.

Planning Considerations:

Geographical Considerations/Description –

This scenario postulates a 10-kiloton improvised nuclear device (IND) detonation in a large metropolitan area. The effects of the damage from the blast, thermal radiation, prompt radiation, and the subsequent radioactive fallout have been calculated, based on a detonation in Washington, DC (details are not provided in this executive summary but are presented in the National Planning Scenarios core document in Appendix 1-A). However, the calculation is general enough that most major cities in the United States can be substituted in a relatively straightforward manner. If the incident happened near the U.S. border, there would be a need for cooperation between the two border governments. Additionally, the IND attack may warrant the closure of U.S. borders for some period of time. If the detonation occurs in a coastal city, the fallout plume may be carried out over the water, causing a subsequent reduction in casualties. On the other hand, the surrounding water will likely restrict the zones that are suitable for evacuation. Bridges and tunnels that generally accompany coastal cities will restrict the evacuation, causing delay and an increase in the radioactive dose that evacuees receive. This delay may be substantial and the resulting dose increase may drive a decision to shelter-in-place or evacuate-in-stages.
Timeline/Event Dynamics –
The response timeline will begin the instant the detonation occurs. Initially, only survivors in the immediate area will conduct rescue and lifesaving activities. Later (minutes to hours), rescue teams will begin to arrive and provide assistance. With the current state of education, training, and equipment, it is likely that many of these responders will subject themselves to very large (perhaps incapacitating or fatal) doses of radiation. As various command posts are set up (which may take hours to days), the response will become more coordinated.

For a nuclear detonation, the actual occurrence of injuries does not stop when the immediate blast effects have subsided. The most critical components of the post-detonation response may not be the lifesaving efforts that assist the victims directly injured by the detonation. Instead, it is likely that the most effective lifesaving activities will be those that address the evacuation or sheltering-in-place decisions for the potential victims in the immediate fallout path, the effective communication of instructions to the affected population, and the efficient decontamination of the evacuated population.

Mission Areas Activated –

**Prevention/Deterrence:**

Law enforcement attempts will be made to prevent development and detonation of the device. Site boundaries must be protected and surveyed after the detonation. Officers must respond to any additional threats or looting/theft issues.

**Emergency Assessment/Diagnosis:**

The detonation will be easily recognized as nuclear. Actions required include dispatching response units; making incident scene reports; detecting and identifying the source; establishing a perimeter; collecting information; making hazard assessments and predictions; coordinating hospital and urgent care facilities; coordinating County and State response requests; and coordinating monitoring, surveying, and sampling operations.

**Emergency Management/Response:**

Evacuation/shelter-in-place decisions must be made immediately. Required actions include alerting the public, providing traffic and access control, protecting at-risk and special populations, supporting requests for assistance, directing and controlling critical infrastructure assets, and directing public information activities. Location and removal of injured and disabled people will be a significant undertaking that will be greatly complicated by the need to keep the radiation dose of the individual workers as low as reasonably achievable (ALARA). Initial emergency workers will likely receive high doses of radiation and must be trained on how to avoid as much as possible.

**Hazard Mitigation:**

Self-evacuation should occur in the short-term, and the greatest factor impacting the reduction of the effects of the detonation on the general population will remain the speed and appropriateness of the decisions that are made and the effectiveness of the dissemination of this information (e.g., evacuation/shelter-in-place instructions). Evacuees must be promptly decontaminated.

**Evacuation/Shelter:**

Evacuation and/or sheltering of downwind populations will be required. Actions of the incident-site, local-area, and EOC personnel should include monitoring and decontaminating evacuees, protecting schools and day care facilities, and providing shelter/reception.
Executive Summaries

Scenario 1: Nuclear Detonation – 10-kiloton Improvised Nuclear Device

Victim Care:
Tens of thousands will require decontamination and both short-term and long-term treatment. Due to a high number of casualties, the level of care may be significantly lower than normally expected. When overwhelmed with victims who need care, decisions must be made based on the fact that the sooner the onset of the symptoms, the higher the dose received and the less likely the victim is to survive (even with medical intervention).

Investigation/Apprehension:
Attribution activities at the detonation site will rely largely on scientific forensic techniques and will be provided by specialized national teams. Actions of incident-site personnel will include site control and criminal investigation. Federal authorities or the military will probably conduct “apprehension” activities.

Recovery/Remediation:
Expected radiation levels will limit the total time workers can spend in the affected area, quickly leading to a shortage of willing, qualified, and trained workers. The volume of contaminated material that will be removed will overwhelm the national hazardous waste disposal facilities and will severely challenge the Nation’s ability to transport the material. This effort will be the most expensive and time-consuming part of recovery and will likely cost many billions of dollars and take many years.

Key Implications:
A full description of the fatalities and injuries for a nuclear detonation is difficult and complicated. There will be casualties directly associated with the blast, which will cause “translation/tumbling” (the human body being thrown) and subsequent impacts of people and other objects. A nuclear detonation will also produce a great deal of thermal (heat) energy that will cause burns to exposed skin (and eyes). There are two general “categories” of nuclear radiation produced in a detonation. First is the so-called “prompt” nuclear radiation, arbitrarily defined as being emitted within the first minute – it is actually produced as the device detonates or shortly thereafter. For a 10-kiloton blast, this radiation may expose unprotected people within a distance of a few kilometers (a couple of miles) to extremely large gamma ray and/or neutron doses. In addition, a detonation of a nuclear device near the surface of the ground will result in a great deal of fallout (in the form of dirt particles) that is radioactively contaminated. This fallout will settle out of the radioactive cloud over a period of time, mostly in the first weeks. By far, the most dangerously radioactive fallout will be deposited near the detonation site and will happen within the first couple of hours after detonation. Radioactive fallout will exponentially decay with time, but may expose many people to large doses and will certainly contaminate large areas of land for years. Many fatalities and injuries will result from a combination of these various effects.

The largest radiation concerns following an IND incident will be the “prompt” radiation (gamma ray and neutron) and the gamma dose received from the “ground shine” (radioactive particles deposited on the ground) as people are evacuated from the fallout areas. These effects are likely to have significantly larger impacts on the population than internal doses. Internal doses tend to expose the body to relatively small radiation doses over a long period of time, which produces different effects than large radiation doses received during a short period of time.
As the distance from ground zero increases past 20 kilometers (~ 12 miles), the injuries due to acute radiation exposure (i.e., from prompt radiation and the subsequent fallout) will decrease, and lower level contamination, evacuation, and sheltering issues will become the major concern. In general, at distances greater than 250 kilometers (~ 150 miles) from ground zero of a 10-kiloton nuclear detonation, acute health concerns will not be a significant issue. However, contamination of people and the environment will still be a concern.

Years later, there will still be health consequences in the form of increased probabilities of cancers in the exposed population. The number of these cancers will likely run into the thousands and will extract a large human, social, and financial cost.

It is likely that the blast and subsequent fires will destroy all buildings in the immediate area of the detonation. Historically, decontamination of sites involves the removal of all affected material, so most buildings in the immediate downwind fallout path will likely have to be destroyed in the decontamination effort. As the distance from the detonation site increases, the contamination level will decrease. At some distance, the buildings will not have to be destroyed and removed but will still require decontamination of all affected surfaces. This decontamination process will take years and will be extremely expensive. The decontamination will produce a far greater challenge and cost much more than the actual rebuilding of the destroyed structures. Up to approximately 8,000 square kilometers (~ 3,000 square miles) of land will have to undergo varying degrees of decontamination. This effort will last for many years and will cost many billions of dollars to complete.

Service disruption will be extensive in the area near ground zero and in the fallout path for several miles downwind. Services in these areas will not be restored for years because the land affected will not be returned to use until the decontamination is complete and the structures rebuilt. Service disruption will be much less dramatic in areas that are less severely contaminated or not contaminated at all.

The electrical power grid is likely to be damaged by transients produced by the destruction of substations, as well as other power production and distribution installations, and perhaps by the EMP of the detonation. It is likely that the grid damage may cause power outages over wide areas, perhaps over several States, but these outages should be repaired within several days to a couple of weeks. The communication systems in the area will suffer similar damage and will likely be repaired within similar timeframes.

City water mains will likely survive without major damage. The city water supply is unlikely to become substantially contaminated with radiation via water main breaks; however the effects of radioactive and non-radioactive contamination may enter the lines and impact the water supply.

To varying degrees, all Government services will be impacted over some geographical area. The national economy will be significantly impacted. Decontamination, disposal, and replacement of lost infrastructure will cost many billions of dollars. Replacement of lost private property and goods could add billions more to the cost. Additionally, an overall national economic downturn, if not recession, is probable in the wake of the attack.

Scenario 1: Nuclear Detonation – 10-kiloton Improvised Nuclear Device

1-4
**Note:** For more information, there are two appendices – available only in the *National Planning Scenarios* core document – that provide more detailed information regarding results. Appendix 1-A contains a consequence report for a 10-kiloton nuclear detonation in Washington, DC, that describes a set of possible consequences calculated for a 10-kiloton nuclear blast including its prompt effects (occurring within the first minute) and fallout. Appendix 1-B, Estimated “Realistic” Results, reflects a set of possible results from the 10-kiloton detonation described in this scenario. The results provided in Appendix 1-A are very conservative, and the results provided in Appendix 1-B are less conservative and are intended to be more realistic.

Scenario General Description:
Anthrax spores delivered by aerosol delivery results in inhalation anthrax, which develops when the bacterial organism, *Bacillus anthracis*, is inhaled into the lungs. A progressive infection follows. This scenario describes a single aerosol anthrax attack in one city delivered by a truck using a concealed improvised spraying device in a densely populated urban city with a significant commuter workforce. It does not, however, exclude the possibility of multiple attacks in disparate cities or time-phased attacks (i.e., “reload”). For Federal planning purposes, it will be assumed that the Universal Adversary (UA) will attack five separate metropolitan areas in a sequential manner. Three cities will be attacked initially, followed by two additional cities 2 weeks later.

Planning Considerations:

Geographical Considerations/Description –
Dispersal of the anthrax takes place in a densely populated urban city with a significant commuter workforce. The exposed population will disperse widely before the incident is detected.

Timeline/Event Dynamics –
It is possible that a Bio-Watch signal would be received and processed, but this is not likely to occur until the day after the release. The first cases of anthrax would begin to present to Emergency Rooms (ERs) approximately 36 hours post-release, with rapid progression of symptoms and fatalities in untreated (or inappropriately treated) patients.

The situation in the hospitals will be complicated by the following facts: The release has occurred at the beginning of an unusually early influenza season and the prodromal symptoms of inhalation anthrax are relatively non-specific. Physician uncertainty will result in low thresholds for admission and administration of available countermeasures (e.g., antibiotics), producing severe strains on commercially available supplies of such medications as ciprofloxacin and doxycycline, and exacerbating the surge capacity problem.
Mission Areas Activated –

**Prevention/Deterrence:**
This area requires knowledge of those with the ability to grow and aerosolize anthrax, reconnaissance of equipment and laboratories, and public health protection measures.

**Emergency Assessment/Diagnosis:**
It will be necessary to monitor attack impact, determine resource needs, classify the type of event, and identify other events (if any). Environmental sampling for exposure risk assessment, identification of anthrax strain, and determination of any drug resistance will also be required.

**Emergency Management/Response:**
Management and response will require public alerts, mobilization of the Strategic National Stockpile, activation of treatment sites, traffic/access control, special population protection, protective measures (e.g., shelter-in-place), requests for resources and assistance, and public information activities.

**Hazard Mitigation:**
Mitigation will require Prepositioned Equipment Pods (PEP) and personal protective equipment (PPE) provision, environmental testing/decontamination, care of ill persons, victim treatment, site remediation and monitoring, notification of airlines/transport providers, public information provision, and coordination with public health agencies.

**Evacuation/Shelter:**
Evacuation and treatment of victims will be required. JIC will coordinate efforts to provide warnings to the population-at-large and the population-at-risk, and will notify people to shelter-in-place and/or evacuate.

**Victim Care:**
Care to the ill must be provided and should include disbursing PEP/vaccinations and establishing treatment/distribution centers.

**Investigation/Apprehension:**
Law enforcement will investigate the attack in collaboration with public health officials working to identify populations at risk of disease. This also requires epidemiological trace-back of victims, parallel criminal investigations, and laboratory analyses.

**Recovery/Remediation:**
The Environmental Protection Agency (EPA) and the CDC will coordinate this area. Extensive decontamination and cleanup will be required (anthrax is long-lived in the environment) costing billions of dollars. Remediation will also require environmental testing, highly contaminated area closures, and public information provision.

Key Implications:
This attack results in 328,484 exposures; 13,208 untreated fatalities; and 13,342 total casualties. Although property damage will be minimal, city services will be hampered by safety concerns.

There is the potential for a sell-off in the economic markets; moreover, the stock exchange and large businesses may be directly affected by the attack. There may also be a decline in consumer spending and a loss of revenue for the metropolitan area. An overall national economic downturn is possible in the wake of the attack due to loss of consumer confidence. The costs of the closure of a large section of the city and the decrease in revenue from tourism for an indeterminate period would be enormous, as would the costs of remediation and decontamination.
Scenario 3: Biological Disease Outbreak – Pandemic Influenza

**Executive Summary**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**Scenario General Description:**

Influenza pandemics have occurred every 10 to 60 years, with three occurring in the twentieth century (1918, 1957-1958, and 1967-1968). Influenza pandemics occur when there is a notable genetic change (termed genetic shift) in the circulating strain of influenza. Because of this genetic shift, a large portion of the human population is entirely vulnerable to infection from the new pandemic strain. This scenario hypothetically relates what could happen during the next influenza pandemic without an effective preplanned response.

**Planning Considerations:**

**Geographical Considerations/Description –**

The two most important geographic considerations for pandemic influenza are that it occurs almost everywhere and that it moves extremely rapidly. (For example, in 1918, well before the advent of commercial passenger aviation, pandemic influenza spread across the United States within a 6- to 8-week period.) Few, if any, medical personnel, medical equipment, or similar resources will be available for redistribution. In the United States, State, city, and local governments, as well as health care systems, essentially will have to cope using already existing resources. Obviously, available medical supplies, such as vaccines and drugs, will be distributed as available. But health care systems will not, for example, be able to “borrow” additional health personnel from the neighboring city or State.

**Timeline/Event Dynamics –**

When planning and preparing for the next influenza pandemic, there are two equally important timelines. Due to the rapid spread of the influenza pandemic and the time required to develop, test, produce, and distribute an effective vaccine, the disease will likely arrive in the United States before a “significant” number of people can be vaccinated. The implication of this is that, as part of any pandemic influenza preparation and response plan, there must be a mechanism for allocating the vaccine among the population.

---

1 Adapted from Patriarcia et al., *Pandemic influenza: A planning guide for state and local officials (draft 2.1)*. Available online at http://www.cdc.gov/od/nvpo/pubs/pandemicflu.htm.
### Mission Areas Activated –

#### Prevention/Deterrence:
Prevention is currently impossible. Protection requires pre-pandemic preparedness, providing more vaccines and conducting more vaccine research and development, antiviral drug stockpiling, and increased surveillance capacity to track illness patterns.

#### Preparedness:
Pre-pandemic preparedness activities largely refer to the capacity to deal with the impact (see Emergency Management/Response). Another possible pre-pandemic activity is the stockpiling of influenza antiviral drugs. However, the amount of drugs stockpiled will depend on selected goals. However, widespread use of antiviral drugs could cause antiviral-resistant strains of pandemic influenza to begin to circulate, which would limit the effective lifespan of these drugs.

#### Emergency Assessment/Diagnosis:
U.S. influenza surveillance systems will be activated. However, more information is needed regarding attack rate measurements.

#### Emergency Management/Response:
Preparedness plans should contain clear guidelines on setting priorities for the use of scarce resources such as vaccines, drugs, and hospital beds. Federal and State Governments have such plans in progress but not all are complete.

#### Hazard Mitigation:
Success depends on the availability of scarce resources and how well these resources are distributed. Timely, effective public information communication is also important.

#### Evacuation/Shelter:
Evacuations will most likely have no meaningful effect on the spread of disease, and probably will be counter-productive. Quarantine has not typically been used with much success to stop the spread of influenza.

#### Victim Care:
Will rely on the use of antiviral drugs for treatment. Hospitalization and mechanical ventilators will be necessary for many and likely be in short supply. However, at-home care and over-the-counter medications may be helpful for some. A large number of fatalities will likely occur, requiring mortuary and burial services. The U.S. Department of State’s Bureau of Consular Affairs will need to be involved.

#### Investigation/Apprehension:
Investigation is dependent on disease surveillance, although the current system has distinct limitations.
Key Implications:

Estimates of impact are provided in Table 3-1.

<table>

</table>

*Percent Gross Attack Rate refers to the percentage of the entire U.S. population that will have a clinical case of influenza.

Note: Assumptions for these estimates are available in the National Planning Scenarios core document, which also includes an Appendix 3-C that provides graphs and additional estimates.

Table 3-1. Mean estimates (5th, 95th percentiles) of the impact of the next influenza pandemic in the United States without any large-scale and/or effective interventions

Property damage is minimal. Service disruption, however, could be severe due to worker illness. Health care systems will be severely stressed, if not overwhelmed, and first responders are also likely to be severely strained.

Based on the estimates in Table 3-1, the economic impact, in 2004 U.S. dollars, will range from $87 billion (15% gross attack rate) to $203 billion (35% gross attack rate). These estimates include a value for time lost from work but do not include any estimate due to economic disruption or long-term health care costs.
Scenario 4: Biological Attack – Plague

Scenario General Description:

Plague is a bacterium that causes high mortality in untreated cases and has epidemic potential. It is best known as the cause of Justinian’s Plague (in the middle sixth century) and the Black Death (in the middle fourteenth century), two pandemics that killed millions. In this scenario, members of the Universal Adversary (UA) release pneumonic plague into three main areas of a major metropolitan city – in the bathrooms of the city’s major airport, at the city’s main sports arena, and at the city’s major train station.

Planning Considerations:

Geographical Considerations/Description –

Although the release will occur only in Major City, rapid dissemination to distant locations through foreign and domestic travel is included in this scenario. Countries with recognized plague outbreaks will be subject to international travel restrictions. Intense communication and cooperation between U.S. and Canadian foreign affairs entities will be required in order to address potential border restrictions as well as citizen and resident health issues. Following a release in the environment, plague may become established within animal populations (e.g., rats), which then pose a risk of ongoing exposure to humans through bites of arthropod vectors.

Timeline/Event Dynamics –

Plague cases rapidly occur in the United States and Canada. As a result of foreign and domestic travel, rapid dissemination to distant locations occurs. By Day 3, the plague spreads across both the Pacific and Atlantic oceans and by Day 4, the plague is confirmed in eleven countries other than the United States and Canada.

Mission Areas Activated –

Prevention/Deterrence: This area requires knowledge of persons with the skills to grow and aerosolize plague, reconnaissance of supplies and laboratories, and public health protection measures.

Emergency Assessment/Diagnosis: Although health professionals should rapidly recognize the
seriousness of the incident, diagnosis of the plague may be delayed. Detection of the plague should initiate laboratory identification of the strain and a determination of the potentially known antimicrobial drug resistance. Origin of the initial contaminant should be traced back to the source.

**Emergency Management/Response:** Identification of drug-resistant plague strains would require full utilization of personal protective equipment (PPE) and quarantine measures. Response will require provision of public alerts, mobilization of the National Strategic Stockpile, activation of treatment sites, traffic and access control, protection of special populations, potential quarantine measures including shelter-in-place recommendations, requests for resources and assistance, and public information activities. Effective communication between U.S. and the eleven countries of traveler destination is vital.

**Hazard Mitigation:** Victims must receive antibiotic therapy within 24 hours to prevent fatality. Exposed victims must be isolated and minimizing disease spread will require epidemiological assessments, including contact investigation and notification.

**Evacuation/Shelter:** Evacuation and treatment of some victims will be required. Self-quarantine through shelter-in-place may be instituted.

**Victim Care:** Victims will require treatment or prophylaxis with ventilators and antibiotics, as well as information measures for preventing spread of the disease. Advanced hospital care will be required for those with pneumonia. The U.S. Department of State's Bureau of Consular Affairs will need to be involved.

**Investigation/Apprehension:** Point-of-source exposures and plague strain must be determined using victim trace-back, criminal investigation, and laboratory analyses.

**Recovery/Remediation:** Extensive decontamination and cleanup will not be necessary because plague cannot live long in the environment and is not viable when exposed to heat and sunlight. However, some efforts should be undertaken to support political/public confidence.

**Key Implications:**

The total number of illnesses at the end of the ninth day is approximately [6,000]. The total number of fatalities is [XXXX]. Assumptions affecting these figures include length of incubation period following primary exposure, rate of secondary transmission, incubation period following secondary exposure, and timing and effectiveness of the intervention (e.g., respiratory precautions and antimicrobial treatment).

Although the actual physical damage to property will be negligible, there will be an associated negative impact of buildings and areas that were or could have been contaminated. Service disruption will be significant for call centers, pharmacies, and hospitals due to overwhelming casualty needs. It will be necessary to close or restrict certain transportation modes. The threat of reduced food supply will cause food prices to rise.

*Scenario 4: Biological Attack – Plague*
A huge sell-off in the economic markets is possible, and loss of life will result in a decline in consumer spending and subsequent loss of revenue in the metropolitan area. An overall national economic downturn is possible in the wake of the attack due to loss of consumer confidence.

Many people will be killed, permanently disabled, or sick as a result of the plague. The primary illness will be pneumonia, although the plague can also cause septicemia, circulatory complications, and other manifestations. The long-term effects of antimicrobial prophylaxis in large numbers will require follow-up study. The associated mental health issues relating to mass trauma and terrorism events will also require assessment.
Scenario 5: Chemical Attack – Blister Agent

Casualties
150 fatalities; 70,000 hospitalizations

Infrastructure Damage
Minimal

Evacuations/Displaced Persons
More than 100,000 evacuated
15,000 seek shelter in immediate area (decontamination required)

Contamination
Structures affected

Economic Impact
$500 million

Potential for Multiple Events
Yes

Recovery Timeline
Weeks; many long-term health effects

Scenario General Description:
Agent YELLOW, which is a mixture of the blister agents sulfur Mustard and Lewisite, is a liquid with a garlic-like odor. Individuals who breathe this mixture may experience damage to the respiratory system. Contact with the skin or eye can result in serious burns. Lewisite or Mustard-Lewisite also can cause damage to bone marrow and blood vessels. Exposure to high levels may be fatal.

In this scenario, the Universal Adversary (UA) uses a light aircraft to spray chemical agent YELLOW into a packed college football stadium. The agent directly contaminates the stadium and the immediate surrounding area, and generates a downwind vapor hazard. The attack causes a large number of casualties that require urgent and long-term medical treatment, but few immediate fatalities occur.

Planning Considerations:

Geographical Consideration/Description –
For purposes of estimating Federal response requirements, the stadium is assumed to be a major college football stadium in an urban area. Examples include Ohio Stadium on the grounds of Ohio State University in Columbus, Ohio; and the Rose Bowl in Pasadena, California, each of which have a seating capacity of approximately 100,000 people. However, the size and location of the stadium and maximum occupancy can be adjusted to meet local conditions.

Timeline/Event Dynamics –
The total time of the attack, including the last mile of the plane’s approach, is less than 5 minutes. The crowd will panic and immediately evacuate the stadium, which will require up to 30 minutes. First responders should begin arriving at the facility perimeter within 10 to 15 minutes of the attack. In order for the UA to succeed in this attack, certain meteorological conditions – wind speed, temperature, humidity, and precipitation – must be met.
Mission Areas Activated –

Prevention/Deterrence: The ability to prevent the attack is contingent on the prevention of chemical warfare material (CWM) acquisition, CWM importation, weapon assembly, plane and pilot acquisition, and site reconnaissance.

Emergency Assessment/Diagnosis: Hazardous material (HazMat) teams should instantly recognize the attack. Liquid contamination and a downwind vapor hazard will be components of the hazard. Actions required include dispatch; agent detection; and hazard assessment, prediction, monitoring, and sampling.

Emergency Management/Response: Actions required include alerts, activation and notification, traffic and access control, protection of special populations, resource support and requests for assistance, and public information activities.

Hazard Mitigation: The spread of contamination by fleeing victims will be a major challenge. Actions required include isolating and defining the hazard; establishing, planning, and operating incident command; preserving the scene; conducting mitigation efforts; decontaminating responders; and conducting site remediation and monitoring.

Evacuation/Shelter: Evacuation and/or sheltering of downwind populations in a 360-degree arc around the stadium will be required until the stadium is decontaminated.

Victim Care: Tens of thousands of people will require decontamination and both short- and long-term medical treatment.

Investigation/Apprehension: Actions required include aircraft tracking, dispatch, site control, criminal investigation, tactical deployment, and suspect apprehension.

Recovery/Remediation: The stadium and adjacent facilities must be decontaminated of liquid agent YELLOW. Decontamination waste disposal is complicated by the presence of arsenic. Environmental testing must be done. Although decontamination could technically restore the stadium, psychological impact will likely require the stadium to be rebuilt.

Key Implications:

In the case of a full, 100,000-seat stadium, 70,000 people (70%) may be contaminated in the attack. Of these, most will have only clothing and/or skin contamination, resulting in moderate-to-severe skin blisters that will appear in 2 to 12 hours. Expedient decontamination (i.e., clothing removal and heavy water spray) will avoid half of these injuries. Systemic arsenic poisoning will occur in highly contaminated individuals. However, many will inhale sufficient agent vapor to cause severe lung damage, and many more will sustain permanent damage to the eyes. Fatalities and major injuries will occur due to falling and crushing during the evacuation, and to vehicle accidents.

There will be little direct property damage due to the attack. However, the stadium site and other contaminated property will be a total loss due to decontamination measures and/or psychological impacts of future usability.
Loss of use of the stadium and adjacent athletic facilities is expected. Additionally, some public transportation and other facilities may be lost due to contamination carried by fleeing victims. Overwhelming demand will disrupt communications (landline telephone and cellular) in the local area. Finally, some victims may self-transport to health care facilities and could possibly contaminate those facilities.

Decontamination, destruction, disposal, and replacement of a major stadium could cost up to $500 million. Enrollment at the college will be negatively affected, and the local community will experience significant losses resulting from the attack. Additionally, an overall national economic downturn is possible in the wake of the attack due to a loss of consumer confidence.

Many will be permanently blinded and many more will carry lifetime scars. Many may suffer significant damage to the lungs. In addition, Mustard is a known carcinogen, and systemic poisoning from the arsenic in Lewisite is also a concern.
Scenario 6: Chemical Attack – Toxic Industrial Chemicals

Executive Summary

### Casualties
350 fatalities; 1,000 hospitalizations

### Infrastructure Damage
50% of structures in area of explosion

### Evacuations/Displaced Persons
- 10,000 evacuated
- 1,000 seek shelter in safe areas
- 25,000 instructed to temporarily shelter-in-place as plume moves across region
- 100,000 self-evacuate out of region

### Contamination
Yes

### Economic Impact
Billions of dollars

### Potential for Multiple Events
Yes

### Recovery Timeline
Months

Scenario General Description:

In this scenario, terrorists from the Universal Adversary (UA) land in several helicopters at fixed facility petroleum refineries. They quickly launch rocket-propelled grenades (RPGs) and plant improvised explosive devices (IEDs) before re-boarding and departing, resulting in major fires. At the same time, multiple cargo containers at a nearby port explode aboard or near several cargo ships with resulting fires. Two of the ships contain flammable liquids or solids. The wind is headed in the north-northeast direction, and there is a large, heavy plume of smoke. The smoke is visible drifting east into heavily populated areas. Releases of cobalt, nickel, molybdenum, cadmium, mercury, vanadium, platinum, and other metals have occurred in the plumes. One of the burning ships in the port contains resins and coatings including isocyanates, nitriles, and epoxy resins. Some IEDs are set up for remote detonation. Casualties occur onsite due to explosive blast and fragmentation, fire, and vapor/liquid exposure to the toxic industrial chemical (TIC). Downwind casualties occur due to vapor exposure.

Planning Considerations:

**Geographical Considerations/Description –**
Size and location of the port and downwind population at risk can be adjusted to meet local conditions. A river port or a large rail facility could be substituted for the port for inland jurisdictions. The ability to obtain several helicopters would seem to be limiting, however.

**Timeline/Event Dynamics –**
Total time to plan and prepare for the attack would be on the order of 2 years, including reconnaissance, pilot and weapons training, and accumulation of weapons. Time to execute the attack would be several weeks to coordinate the shipping and coincident arrival of the containers aboard separate ships at the port. Time to execute the airborne phase of the attack would be on the order of 1 to 2 hours from liftoff from the originating airport. Time over target for the helicopters would be about 10 minutes. Time on the ground would be 2 to 3 minutes at each site. Fires resulting from the attack would take many hours, possibly days, to extinguish. In order for
the UA to succeed in this attack, certain meteorological conditions – wind speed, temperature, humidity, and precipitation – must be met.

**Mission Areas Activated –**

**Prevention/Deterrence:**
Avoiding an attack would require prevention of aircraft and weapons acquisition, IED assembly, and site reconnaissance.

**Emergency Assessment/Diagnosis:**
The presence of multiple chemicals and exposure symptoms will greatly complicate assessment and identification efforts. Actions required include dispatch; TIC detection; and hazard assessment, prediction, monitoring, and sampling.

**Emergency Management/Response:**
Actions required include alerts, activation and notification, traffic and access control, protection of special populations, resource support and requests for assistance, and public information activities.

**Hazard Mitigation:**
Mitigation measures will be complicated by multiple TICs and secondary device concerns. Actions required include isolating and defining the hazard; establishing, planning, and operating incident command; firefighting; performing bomb disposal dispatch and IED render-safe procedures; preserving the scene; conducting mitigation efforts; decontaminating responders; and performing site remediation and monitoring.

**Evacuation/Shelter:**
Evacuation/sheltering/protection of downwind populations will be required.

**Victim Care:**
Injuries to be treated will include trauma, burns, smoke inhalation, severe respiratory distress, seizures, and/or comas. Short- and long-term treatment will be required as well as decontamination.

**Investigation/Apprehension:**
Searching for suspects and evidence in an industrial area while wearing personal protective equipment (PPE) will be a significant challenge. Actions required include dispatch, site control, criminal investigation, pursuit and tactical deployment, and apprehension of suspects.

**Recovery/Remediation:**
The extent of decontamination required will depend on the TIC. Regardless, monitoring and sampling a large industrial port facility and refineries will be a challenge. Site restoration will be a major challenge, particularly for the refineries. Environmental impact issues are likely to significantly delay rebuilding efforts.

**Key Implications:**
Assuming a densely populated area, 7,000 people may be in the actual downwind area. Of these, 5% (350) will receive lethal exposures, and half of these will die before or during treatment. An additional 15% will require hospitalization, and the remainder will be treated and released at the scene by Emergency Medical Service (EMS) personnel. However, approximately 70,000 “worried well” may seek treatment at local medical facilities.

All three refineries sustain significant damage, with 50% of the equipment and facilities requiring significant repairs or replacement. Two ships in the port sink at their moorings; the port sustains heavy damage near the ships and at a dozen points where IEDs were dropped.
Depending on which chemicals are released, there may be significant property damage in the downwind area.

Refinery capacity on the West Coast is significantly diminished, resulting in fuel shortages and price increases. The port is temporarily closed due to damage and contamination. Contamination in the waterway may also result. Some public transportation and other facilities may be lost. Overwhelming demand will disrupt communications (landline telephone and cellular) in the local area. Significant disruptions in health care occur due to the overwhelming demand of the injured and the “worried well.” Authorities will need to verify portability of the water supply.

Decontamination, destruction, disposal, and replacement of major portions of the refineries could cost billions of dollars. Similar costs could be expected at the port. Loss of the port will have a significant impact on U.S. trade with the Pacific Rim. An overall national economic downturn is possible in the wake of the attack due to a loss of consumer confidence.

In addition to their toxic effects, many TICs are known carcinogens. Long-term damage to internal organs and eyes is possible, depending on which TICs are present.
Scenario 7: Chemical Attack – Nerve Agent

Executive Summary

<table>
<thead>
<tr>
<th>Casualties</th>
<th>5,700 fatalities (95% of building occupants); 300 injuries</th>

</tbody>
</table>

Scenario General Description:

Sarin is a human-made chemical warfare agent classified as a nerve agent. Nerve agents are the most toxic and rapidly acting of the known chemical warfare agents. They are similar to certain kinds of pesticides (insect killers), called organophosphates, in terms of how they work and what kind of harmful effects they cause. However, nerve agents are much more potent than organophosphate pesticides. Sarin is a clear, colorless, odorless, and tasteless liquid in its pure form. However, Sarin can evaporate into a vapor and spread into the environment. Sarin is also known as GB.

In this scenario, the Universal Adversary (UA) releases Sarin vapor into the ventilation systems of three large commercial office buildings in a metropolitan area. The agent kills 95% of the people in the buildings, and kills or sickens many of the first responders. In addition, some of the agent exits through rooftop ventilation stacks, creating a downwind hazard.

Planning Considerations:

Geographical Considerations/Description –
Size, location, and maximum occupancy of the building can be adjusted to meet local conditions. For purposes of estimating Federal response requirements, each building is assumed to have an occupancy of 2,000 personnel (e.g., twenty-story buildings with 100 occupants per floor), and the outdoor/subway population density of the surrounding areas is 3,900 people per square mile (one-tenth of the total population density in the vicinity of Times Square, New York).

Timeline/Event Dynamics –
The attack will require 6 months to plan, including putting the faux janitors in place, shipping the agent, and fabricating the spray devices. Once all is ready, the janitors will take less than 10 minutes to retrieve the sprayers from the courier vans, emplace them, and activate them. First responders should arrive at the facility within 10 to 15 minutes of the attack. In order for the UA to succeed in this attack, certain meteorological conditions – wind speed, temperature, humidity, and precipitation – must be met.
Mission Areas Activated –

Prevention/Deterrence: The ability to prevent the attack is contingent on the prevention of CWM importation, weapons assembly, and site reconnaissance.

Emergency Assessment/Diagnosis: Rapid recognition of an attack will be key to avoiding first responder casualties. Actions required include dispatch; agent detection; and hazard assessment, prediction, monitoring, and sampling.

Emergency Management/Response: Actions required include alerts, activation and notification, traffic and access control, protection of special populations, resource support and requests for assistance, and public information activities.

Hazard Mitigation: Actions required include isolating and defining the hazard; establishing, planning, and operating incident command; preserving the scene; conducting mitigation efforts; decontaminating responders, and conducting site remediation and monitoring.

Evacuation/Shelter: Evacuation and/or sheltering of downwind populations will be required.

Victim Care: Tens of thousands of persons will require monitoring and decontamination as they are allowed to leave their buildings. Hundreds will require hospital treatment.

Investigation/Apprehension: Tracking and apprehension of the suspects will be included. Actions required include suspect tracking and apprehension, dispatch, site control, criminal investigation, and tactical deployment.

Recovery/Remediation: Anything exposed to a high-vapor agent concentration will require decontamination, including bodies. There will be little damage to the building as a direct result of the attack. However, decontamination of some materials may be difficult or impossible. Even if structures and property could be technically decontaminated, the psychological impact on future usability would be significant.

Key Implications:

Assuming 2,000 occupants per building, the initial fatality count will be 5,700 (95%) and 300 injured, including the initial Emergency Medical Service (EMS) and fire personnel at each building. Patients who experience prolonged seizures may sustain permanent damage to the central nervous system – assume 350 patients in this category (300 inside plus 50 outside). Fatalities and major injuries will occur due to falling and crushing during the panic on the street, and due to vehicle accidents.

Little direct damage due to the attack, except the building interiors and contents, will be highly contaminated by agent condensing on surfaces. The three buildings and their contents will be a total loss due to decontamination measures and/or psychological impacts of future usability. However, airing and washing should decontaminate adjacent structures adequately.

Overwhelming demand will disrupt communications (landline telephone and cellular) in the local area. There will be large numbers of “worried well” swamping the medical system. Loss of three fire crews and three EMS crews will impact readiness for other events in the short term.
Decontamination, destruction, disposal, and replacement of three large commercial office buildings could cost up to $300 million. Business in the buildings may never reopen, and an overall national economic downturn is possible in the wake of the attack due to loss of consumer confidence.

Those who survive usually recover within 4 to 6 weeks, with full cholinesterase level restoration within 3 to 4 months. Patients who experience prolonged seizures may sustain permanent damage to the central nervous system.
Scenario 8: Chemical Attack – Chlorine Tank Explosion

Executive Summary

<table>
<thead>
<tr>
<th>Casualties</th>
<th>17,500 fatalities; 10,000 severe injuries; 100,000 hospitalizations</th>
</tr>
</thead>

<tr>
<td>Recovery Timeline</td>
<td>Weeks</td>
</tr>
</tbody>
</table>

Scenario General Description:

Chlorine gas is poisonous and can be pressurized and cooled to change it into a liquid form so that it can be shipped and stored. When released, it quickly turns into a gas and stays close to the ground and spreads rapidly. Chlorine gas is yellow-green in color and although not flammable alone, it can react explosively or form explosive compounds with other chemicals such as turpentine or ammonia.

In this scenario, the Universal Adversary (UA) infiltrates an industrial facility that stores a large quantity of chlorine gas (liquefied under pressure). Using a low-order explosive, UA ruptures a storage tank man-way, releasing a large quantity of chlorine gas downwind of the site. Secondary devices are set to impact first responders.

Planning Considerations:

Geographical Considerations/Description –
Size and location of the chlorine storage facility and downwind population at risk can be adjusted to meet local conditions. Bulk storage of chlorine occurs in tanks as large as 120,000 gallons in the United States.

Timeline/Event Dynamics –
Total time to plan and prepare for the attack would be on the order of 2 years, including reconnaissance and weapons training, and accumulation of weapons. Time to execute the attack would include days to weeks to find the right weather conditions. The actual infiltration, explosive charges setting, and exfiltration would take less than 20 minutes. Except in very cold conditions, the release would be complete in less than an hour. The plume would travel downwind and be dispersed below the detection level in 6 hours. In order for the UA to succeed in this attack, certain meteorological conditions – wind speed, temperature, humidity, and precipitation – must be met.
**Mission Areas Activated –**

**Prevention/Deterrence:** The ability to prevent the attack is contingent on the prevention of weapons acquisition, specifically IEDs, and site reconnaissance.

**Emergency Assessment/Diagnosis:** The presence of secondary devices will complicate assessment and identification efforts. Actions required include dispatch; chlorine detection; and hazard assessment, prediction, monitoring, and sampling.

**Emergency Management/Response:** Actions required include alerts, activation and notification, traffic and access control, protection of special populations, resource support and requests for assistance, and public information activities.

**Hazard Mitigation:** Mitigation measures will be complicated by secondary device concerns (i.e., delayed detonation of IEDs). Actions required include isolating and defining the hazard; establishing, planning, and operating incident command; firefighting; conducting bomb disposal dispatch and IED render-safe procedures; preserving the scene; performing mitigation efforts; decontaminating responders; and conducting site remediation and monitoring.

**Evacuation/Shelter:** Evacuation/sheltering/protection of downwind populations will be required.

**Victim Care:** Injuries to be treated will include respiratory difficulty or severe distress and/or vehicular accident trauma. Short- and long-term treatment may be required.

**Investigation/Apprehension:** Searching for suspects and evidence in an industrial area while wearing personal protective equipment (PPE) will be a significant challenge. Actions required include dispatch, site control, criminal investigation, pursuit and tactical deployment, and apprehension of suspects.

**Recovery/Remediation:** Since chlorine is a gas, the extent of decontamination required will be minor and largely related to any releases generated by secondary devices. Regardless, monitoring and sampling a large industrial facility will be a challenge. There will be significant damage to the plant as a direct result of the attack. Decontamination of waterways may present a significant challenge as well. Environmental impacts, especially public safety concerns, are likely to significantly delay rebuilding efforts.

**Key Implications:**

Assuming a high-density area, as many as 700,000 people may be in the actual downwind area, which could extend as far as 25 miles. Of these, 5% (35,000) will receive potentially lethal exposures, and half of these will die before or during treatment. An additional 15% will require hospitalization, and the remainder will be treated and released at the scene by Emergency Medical Service (EMS) personnel. However, approximately 450,000 “worried well” will seek treatment at local medical facilities.
The storage tank will be lost, along with some sensitive control systems damaged by the freezing liquefied gas. The secondary devices will cause damage to other plant facilities and equipment in a 20-meter radius of the blasts as well. In areas of heavy chlorine exposure, there will also be heavy corrosion of metal objects.

The plant will be temporarily closed due to bomb damage. Overwhelming demand will disrupt communications (landline telephone and cellular) in the local area. Significant disruptions in health care occur due to the overwhelming demand of the injured and the “worried well.” Authorities will need to verify portability of the water supply.

Decontamination, destruction, disposal, and replacement of major portions of the plant could cost millions. The local economy will be impacted by a loss of jobs at the facility if it is unable to reopen.

Most of the injured will recover in 7 to 14 days, except for those with severe lung damage. These individuals will require long-term monitoring and treatment.
Scenario 9: Natural Disaster – Major Earthquake

Executive Summary

</tbody>
</table>

Scenario General Description:

Earthquakes occur when the plates that form under the Earth’s surface suddenly shift, causing binding and pressure, and most earthquakes occur at the boundaries where the plates meet. A fault is a fracture in the Earth's crust along which two blocks of the crust have slipped with respect to each other. The magnitude of an earthquake, usually expressed by the Richter Scale, is a measure of the amplitude of the seismic waves. The intensity, as expressed by the Modified Mercalli (MM) Scale, is a subjective measure that describes how strong a shock was felt at a particular location.

The Richter Scale is logarithmic so that a recording of 7, for example, indicates a disturbance with ground motion ten times as large as a recording of 6. A quake of magnitude 2 is the smallest quake normally felt by people. Earthquakes with a Richter value of 6 or more are commonly considered major; great earthquakes have magnitude of 8 or more. The MM Scale expresses the intensity of an earthquake’s effects in a given locality in values ranging from I to XII. The most commonly used adaptation covers the range of intensity from the condition of “I – Not felt except by a very few under especially favorable conditions,” to “XII – Damage total. Lines of sight and level are distorted. Objects thrown upward into the air.”

In this scenario, a 7.2-magnitude earthquake, with a subsequent 8.0 earthquake following, occurs along a fault zone in a major metropolitan area of a city. MM Scale VIII or greater intensity ground shaking extends throughout large sections of the metropolitan area, greatly impacting a six-county region with a population of approximately 10 million people. Subsurface faulting occurs along 45 miles of the fault zone, extending along a large portion of highly populated local jurisdictions, creating a large swath of destruction. Soil liquefaction occurs in some areas, creating quicksand-like conditions.

Planning Considerations:

Geographical Considerations/Description –

The earthquakes occur in a densely populated urban and suburban area with a past history of earthquake activity. The highest points in the major metropolitan area are approximately 5,000
feet above sea level, and the lowest land elevations are a few feet above sea level. Most of the built environment and the population are located in the lower elevations.

**Timeline/Event Dynamics**
While scientists have been predicting a moderate to catastrophic earthquake in the region sometime in the future, there were no specific indications that an earthquake was imminent in the days and weeks prior to this event.

A 7.5-magnitude earthquake strikes along the seismic zone, causing damage to a large multi-State area of several hundred square miles. Rapid horizontal movements associated with the earthquake shift homes off their foundations and cause some tall buildings to collapse or “pancake” as floors collapse down onto one another. Shaking is exaggerated in areas where the underlying sediment is weak or saturated with water. (Note: In the central and eastern United States, earthquake waves travel more efficiently than in the western United States. An earthquake of a given size in the central and eastern United States may cause damage over a much broader area than the same size earthquake in California.)

Several hours later, a subsequent earthquake of magnitude 8.0 occurs. Based on past events, aftershocks are also possible. Sizeable aftershocks may occur for months after the original jolt.

**Mission Areas Activated –**

- **Emergency Assessment/Diagnosis:** Disaster assessments and aerial reconnaissance are necessary. Using real-time seismic data, the Federal Emergency Management Agency (FEMA) runs an earthquake model to provide a preliminary “best guess” at the level of expected damage, subject to confirmation or modification through remote sensing and field assessments. Assessment teams must be deployed and remote sensing initiated.

- **Emergency Management/Response:** Hazardous material spills must be managed. Emergency medical treatment, shelters, and food must be provided. A Joint Information Center (JIC) is established, and search and rescue teams must be placed on alert, some of which should be activated and deployed. Public utilities and other basic-needs services must be repaired as quickly as possible, and damage assessments should be conducted.

- **Hazard Mitigation:** Federal support will be required to coordinate the development of plans to execute mitigation efforts to lessen the effects of future disasters. Mitigation to minimize or avoid future impacts would largely be an issue for recovery and restoration.

- **Evacuation/Shelter:** Structural engineers are inspecting critical building, bridge, freeway, waste facilities, etc., and inspection teams are deployed to inspect hundreds of homes for safe habitability.

- **Victim Care:** The massive number of injured and displaced persons requires a warning order for the activation of Task Forces for the delivery of mass care and health and medical services. Temporary housing strategies must be considered.

- **Recovery/Remediation:** Hazardous materials will contaminate many areas, and decontamination and site restoration will be a major challenge.
Key Implications:

Approximately 1,400 fatalities occur as a direct result of the earthquakes. More than 100,000 people are injured and continue to overwhelm area hospitals and medical facilities, most of which have sustained considerable damage. Approximately 18,000 of the injured require hospitalization. As many as 20,000 people are missing and may be trapped under collapsed buildings and underground commuter tunnels.

More than 1 million buildings were at least moderately damaged (40% of the buildings) and more than 150,000 buildings have been completely destroyed.

Service disruptions are numerous to households, businesses, and military facilities. Medical services are overwhelmed and functioning hospitals are limited. Fire and Emergency Medical Services (EMS) stations and trucks are also damaged. Bridges and major highways are down or blocked, and damaged runways cause flight cancellations. There are widespread power outages and ruptures to underground fuel, oil, and natural gas lines. Water mains are broken. Wastewater primary receptors are broken, closing down systems and leaking raw sewage into the streets. As a result, public health is threatened.

More than 300,000 households have been displaced, and many businesses have lost employees and customers. The port has been adversely affected in its capacity to provide export/import and loading/unloading capabilities, and damage to vital parts of the communications infrastructure has resulted in limited communications capabilities.

The disruption to the Nation’s economy could be severe because the earthquake impacts major supply and transportation centers. Reconstruction, repairs, disposal, and replacement of lost infrastructure will cost billions of dollars. Replacement of lost private property and goods could also cost billions.
Scenario 10: Natural Disaster – Major Hurricane

Scenario General Description:

Hurricanes are intense tropical weather systems consisting of dangerous winds and torrential rains. Hurricanes often spawn tornadoes and can produce a storm surge of ocean water that can be up to 24 feet at its peak and 50 to 100 miles wide. The most destructive companion of hurricanes is the storm surge.

A typical hurricane is 400 miles in diameter and has an average forward speed of 15 miles per hour (mph) in a range of 0 to 60 mph. The average life span of a hurricane is 9 days in a range of less than 1 day to more than 12 days. Hurricanes’ highest wind speeds are 20 to 30 miles from the center. Hurricane force winds cover almost 100 miles, and gale-force winds of 40 mph or more may cover 400 miles in diameter. A fully developed hurricane may tower 10 miles into the atmosphere.

A hurricane is categorized by its sustained wind intensity on a Saffir-Simpson Hurricane Scale that is used to estimate the potential for property damage and flooding. “Major” hurricanes are placed in Categories 3, 4, or 5 with sustained wind intensities between 111 mph to greater than 155 mph. The most dangerous potential storm would be a slow-moving Category 5 hurricane, making landfall in a highly populated area.

In this scenario, a Category 5 hurricane hits a Major Metropolitan Area (MMA). Sustained winds are at 160 mph with a storm surge greater than 20 feet above normal. As the storm moves closer to land, massive evacuations are required. Certain low-lying escape routes are inundated by water anywhere from 5 hours before the eye of the hurricane reaches land.

Planning Considerations:

Geographical Consideration/Description –

The overall terrain of the MMA is generally low-lying land with topography ranging from flat to gently rolling hills. The coastal plain extends inland for approximately 100 miles. There are numerous bays, inlets, and rivers within the region.
**Timelines/Event Dynamics** –
A tropical storm develops in the Atlantic and is upgraded to a hurricane after 5 days in the open waters. After 4 days, the hurricane has steadied at a dangerous Category 4 level on the Saffir-Simson Hurricane Scale and models indicate a track that includes a possible landfall along the coast adjacent to the MMA within 2 more days. The hurricane reaches its peak as predicted and makes landfall with a direct hit on the MMA and coastal resort towns. The next day the hurricane moves out. The rain associated with the storm has caused rivers to overflow their banks, and several rivers systems are experiencing record flood levels.

**Mission Areas Activated** –

**Preparedness:**
The NHC and the Department of Homeland Security (DHS)/Federal Emergency Management Agency (FEMA) hold numerous video teleconferences with State and Federal emergency officials and provide them with the latest forecasts. As the storm approaches, State and local governments are given increasingly accurate forecasts and assessments of possible impacts. Federal and State emergency management officials pre-position initial response resources outside of the projected path of the storm.

**Emergency Assessment/Diagnosis:**
Assessment is required for infrastructure, rapid needs, search and rescue, health and medical, and navigation. Remote sensing and modeling help determine the extent of the damages.

**Emergency Management/Response:**
Some of the response actions require include search and rescue operations, mortuary services and victim identification, medical system support, debris clearance and management, temporary emergency power, transportation infrastructure support, infrastructure restoration, and temporary roofing.

**Hazard Mitigation:**
Support is required to coordinate the development of plans to execute mitigation efforts that lessen the effects of future disasters. This includes studies to assess flood and coastal erosion and intergovernmental plans to mitigate future damages.

**Evacuation/Shelter:**
State and locals have time to execute evacuation plans. Roads leading from the MMA are overwhelmed, and massive traffic jams hinder the evacuation efforts. Measures will need to be taken to provide for temporary shelter and interim housing. Permanent housing support will also be required.

**Victim Care:**
Care must include medical assistance; shelter and temporary housing assistance; emergency food, water, and ice provision; and sanitary facility provision.

**Recovery/Remediation:**
Hazardous materials will contaminate many areas, and decontamination and site restoration will be a major challenge.

**Key Implications:**
The hurricane results in more than 1,000 fatalities, and 5,000 thousand people have sustained injuries requiring professional treatment. Tourists and residents in low-lying areas were ordered to evacuate 48 hours prior to projected landfall. Twenty-four hours prior to predicted landfall massive evacuations were ordered, and evacuation routes have been overwhelmed.
Major portions of the MMA become flooded. Structures in the low-lying areas are inundated when storm surges reach their peak. Many older facilities suffer structural collapse due to the swift influx of water and degradation of the supporting structural base. Newer facilities and structures survive the influx of water, but sustain heavy damage to contents on the lower levels.

Most all shrubbery and trees within the storm’s path are damaged or destroyed, generating massive amounts of debris. Debris is also generated from structures destroyed from tornadoes and structures that have been destroyed or damaged by the hurricane. Many structures will need to be demolished.

Service disruptions are numerous. Shelters throughout the region are also filled to capacity. Hundreds of people are trapped and require search and rescue. Until debris is cleared, rescue operations are difficult because much of the area is reachable only by helicopters and boats. Wind and downed trees have damaged nearly all of the electric transmission lines within the MMA. Most communications systems within the impacted area are not functioning due to damage and lack of power.

Thousands are homeless, and all areas are in serious need of drinking water, and food is in short supply and spoiling due to lack of refrigeration. Sewage treatment plants in the region have been flooded and sustained damaged from the storm. Factories, chemical plants, sewage treatment plants and other facilities in the MMA have suffered severe damage. Hundreds of thousands of gallons of extremely hazardous substances have spilled into the floodwaters. There is also gasoline, diesel fuel, and oil leaking from underground storage tanks. A 95,000-ton tanker struck a bridge, breaching the hull of the vessel, which then began to leak oil into waters adjacent to the MMA. All of these issues threaten public health.

Many businesses have experienced damage to buildings and infrastructure as well as lost employees and customers. Military facilities are damaged, and assistance is needed to provide for the military community and to reconstitute the facilities. The 20-foot storm surge has breached and overtopped flood control and hurricane protection works. All transportation routes are damaged to some degree, and the port facility has also been adversely affected. Many hospitals have sustained severe damage and those that are open are overwhelmed. Schools that are not severely damaged are being used as shelters for the disaster victims. Thousands of pets, domesticated animals, and wild animals have been killed or injured, and officials have been overwhelmed with requests for assistance in finding lost pets.

There are severe economic repercussions for the whole State and region. The impact of closing the port has national implications. The loss of the petro-chemical supplies could raise prices and increase demand on foreign sources.
Scenario 11: Radiological Attack – Radiological Dispersal Devices

Scenario General Description:

In this scenario, the Universal Adversary (UA) purchases stolen cesium chloride (CsCl) to make a radiological dispersal device (RDD), or “dirty bomb.” The explosive and the shielded cesium-137 ($^{137}$Cs) sources are smuggled into the Country. Detonator cord is stolen from a mining operation, and all other materials are obtained legally in the United States. Devices are detonated in three separate, but regionally close, moderate-to-large cities.

$^{137}$Cs is mostly used in the form of CsCl because it is easy to precipitate. CsCl is a fairly fine, light powder with typical particle size median at about 300 microns. Fractions below 10 microns are typically less than 1%. In an RDD, most will fall out within approximately 1,000 to 2,000 feet (although many variables exist), but a small amount may be carried great distances, even hundreds of miles.

Planning Considerations:

**Geographical Considerations/Description** –

Variable winds of 3 to 8 miles per hour carry the radioactively contaminated aerosol throughout an area of approximately thirty-six blocks (the primary deposition zone). Complex urban wind patterns carry the contamination in unpredictable directions, leaving highly variable contamination deposition with numerous hot spots created by wind eddies and vortices. Radioactivity concentrations in this zone are on the order of 5-50 microcuries/m$^2$, with hot spots measuring 100-500 microcuries/m$^2$; however, traces of the $^{137}$Cs plume carry more than 3.5 kilometers (~ 2.2 miles) on prevailing winds. Negative indoor building pressure draws radioactive aerosols into buildings via cracks around windows and doors. Exterior air intakes increase the contamination in the interior of larger buildings. In city one, the subway system is contaminated by radioactive aerosols entering through subway ventilation system air intakes.
Timeline/Event Dynamics –
The attacks have no advance notice or intelligence that indicates their possibility. The explosions are instantaneous, but plume dispersion continues for 20 minutes while breezes navigate the complex environments before particles have fully settled. First responders do not recognize radioactive contamination for 15 minutes in city one. The explosions in cities two and three are promptly identified as “dirty bombs” – this provides some advantage to first responders and government officials in managing contamination on-scene, and in communicating with the public concerning topical contamination and spread of contamination.

Mission Areas Activated –

Prevention/Deterrence:
Efforts should include prevention of trafficking and importation of CsCl and weapon components, detection of the plot, reconnaissance of the site, protection, and deterrence measures.

Emergency Assessment/Diagnosis:
First responders are likely to be contaminated. The downwind aerosol dispersion will be a significant component of the hazard. Assessment and coordination efforts required are numerous.

Emergency Management/Response:
Actions required include mobilizing and operating incident command; overseeing victim triage; stabilizing the site; cordonning the site and managing and controlling the perimeter; providing notification and activation of special teams; providing traffic and access control; providing protection of at-risk and special populations; providing resource support and requests for assistance; providing public works coordination; providing direction and control of critical infrastructure mitigation; and providing public information, outreach, and communication activities.

Hazard Mitigation:
Actions required include isolating the incident scene and defining the hazard areas, building stabilization, providing fire suppression, conducting debris management and radioactive and hazardous contamination mitigation, decontaminating responders and equipment as well as local citizens, and conducting local site contamination control.

Evacuation/Shelter:
Sheltering and/or evacuation of downwind populations will be required and must occur quickly.

Victim Care:
Injured people will require some decontamination in the course of medical treatment and, if possible, prior to hospital admission. Thousands more will likely need superficial decontamination, and both short-term and long-term medical follow-ups.

Investigation/Apprehension:
Actions required include dispatching personnel, conducting site cordonning and control, collecting field data and witness interviews, and performing tactical deployment and apprehension of suspects. Reconstruction of the attack should occur.

Recovery/Remediation:
The extent of contamination will be a major challenge because $^{137}$Cs is highly water-soluble and is chemically reactive with a wide variety of materials, including common building materials such as concrete and stone. Several buildings (those most damaged) will be torn down and eventually rebuilt. Decontamination activities are undertaken for building exteriors and interiors, streets, sidewalks,
Key Implications:

At each site, the blast results in 180 fatalities and about 270 injured requiring medical care. In addition, up to 20,000 individuals in each primary deposition zone potentially have detectable superficial radioactive contamination.

In each blast, one building and twenty vehicles are destroyed, and eight other buildings suffer varying degrees of damage, such as minor structural damage and broken windows. Radioactive contamination is found inside and outside of buildings over an area of approximately thirty-six blocks in each city. Minor contamination may be an issue further downwind as investigators perform more thorough surveys. Most of the subway system in city one is contaminated.

Over the long term, decontamination efforts are expected to be effective, but some property owners choose demolition and rebuilding. Many square blocks will be unavailable to businesses and residents for several years until remediation is completed.

Transportation is severely hampered in each city. Bus, rail, and air transport routes are altered, and officials build highway checkpoints to monitor incoming traffic for contamination. The subway system in city one is completely or partially closed for an extended period. Hospitals in each region, already at maximum capacity with injuries from the blasts, are inundated with up 50,000 “worried well.”

The sewage treatment plant is quickly contaminated. Seventy-five businesses are closed for an extended duration while radioactive contamination is remediated. Local tax revenues plummet, and people discover that insurance claims are rejected. The schools in the contamination zones are closed and students meet in alternate locations. Nearby towns and cities close their doors to residents of the impacted cities for fear of contamination spread.

Decontamination, destruction, disposal, and replacement of lost infrastructure will be costly (i.e., hundreds of millions of dollars per site). The entire contaminated area may be economically depressed for years. An overall national economic downturn may occur in the wake of the attack due to a loss of consumer confidence.

In the long term, no one will suffer acute radiation syndrome, but approximately 20,000 individuals are likely to become externally contaminated at each site. Low-level contamination may enter food and water supplies. The sum of the cumulative exposures results in an increased lifetime cancer risk proportionate to the dose. Mental health services will be required.
Scenario 12: Explosives Attack – Bomb Using Improvised Explosive Devices

Executive Summary

Scenario General Description:

In this scenario, agents of the Universal Adversary (UA) use improvised explosive devices (IEDs) to detonate bombs at a sports arena.

During an event at a large urban entertainment/sports venue, multiple suicide bombers are strategically prepositioned around the arena. They ignite their bombs and self destruct in order to guarantee mass panic and chaotic evacuation of the arena. They also create a large vehicle bomb (LVB) and use suicide bombers in an underground public transportation concourse, and detonate another vehicle bomb in a parking facility near the entertainment complex. Finally, an additional series of devices is detonated in the lobby of the nearest hospital emergency room (ER).

Planning Considerations:

Geographical Considerations/Description –

The incident is primarily designed for an urban environment, but could be adapted for more rural area events such as county fairs and other large gatherings. Casualty estimates would be reduced as a function of a reduced target population and less population density at target points. The primary urban location would be a downtown, high capacity, entertainment center such as the MCI Center in Washington, DC, or the Superdome in New Orleans, Louisiana. The complex would be located within a short distance of an underground public transportation station.

Timeline/Event Dynamics –

The initial suicide bombers self destruct approximately 1 hour after the start of the entertainment event. The detonation of additional explosives is delayed approximately 10 to 15 minutes after the initial suicide bombings in order to allow for detection, evacuation, and response of emergency services providers. The detonation of explosives at the hospital site will be the hardest to time for maximum effect and may need to be coordinated by some communication among cell members. In any case, the hospital device should be detonated before the arrival of casualties from the entertainment venue.
The timing of some of these events, with the exception of the evacuation stimulus, is not critical. The more people who evacuate the venue, the more potential explosives-related casualties are produced. If evacuation of the venue is delayed, the detonation of the LVB near the venue can be expected to produce increased casualties inside the structure due to collapse, secondary and tertiary blast effects, increased exposure to products of combustion, thermal effects, and crowd surge.

**Mission Areas Activated –**

**Prevention/Deterrence:**

The planning and execution of this incident would require a significant level of relatively unsophisticated coordination. As such, the potential for detection in the pre-event planning stages exists.

**Emergency Assessment/Diagnosis:**

The initial suicide bombings are the first recognizable indication that the attack is under way. Actions required include dispatch; agent detection; and hazard assessment, prediction, monitoring, and sampling.

**Emergency Management/Response:**

Actions required include search and rescue, alerts, activation and notification, traffic and access control, protection of special populations, resource support, requests for assistance, and public information. Establishment of a Joint Operations Center (JOC) is required.

**Hazard Mitigation:**

Primary hazards include fire; toxic atmosphere/smoke; un-detonated explosives; unstable structures; electrical hazards; and low visibility. Hospital personnel must ensure that arriving vehicles are not delivery systems for additional weapons.

**Evacuation/Shelter:**

Evacuation is required as well as additional threat assessment. The area must be cordoned.

**Victim Care:**

Injuries range from “walking wounded” to multiple systems trauma, burns, and obvious fatalities. Elimination of the ER facility at the target hospital will force other facilities to receive all patients from the entertainment venue blasts.

**Investigation/Apprehension:**

Investigation can begin during the rescue phase with photo documentation of the immediate scene, victim locations, and injury patterns. Coordination of Federal, State, and local investigative resources will begin early in the incident management.

**Recovery/Remediation:**

Decontamination will be required for debris and remains at all sites and appropriate removal and disposal after evidence search and recovery. Restoration of the main venue could take more than 1 year (depending on the extent of the fire damage). Repair and restoration of the transportation center can be estimated at 4 months.

**Key Implications:**

Casualties will result at all five incident sites and will include civilians, emergency personnel, and the suicide bombers. The LVB detonation outside the venue can be expected to result in the largest number of fatalities and injuries due to the population density expected. Fatalities and injuries are summarized in Table 12-1.
<table>
<thead>
<tr>
<th>Incident or Location</th>
<th>Fatalities</th>
<th>Serious Injuries</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initial suicide bombings</td>
<td>8</td>
<td>150</td>
</tr>
<tr>

<td>Public Transportation Concourse (subway)</td>
<td>8</td>
<td>50</td>
</tr>
<tr>
<td>Hospital ER</td>
<td>8</td>
<td>40</td>
</tr>
</tbody>
</table>

**Table 12-1. Summary of fatalities and serious injuries as a result of the bombings**

Property damage would include blast damage to the entertainment venue, blast damage to buildings across from the entertainment venue, moderate damage to the transportation center, severe damage to vehicles and nearby buildings at the parking facility, and severe damage to the hospital ER.

Service disruption would be severe in the impacted city and would include traffic (especially the subway), public transportation, emergency services, and hospitals. The local economic impact includes loss of use of the entertainment venue for a period of 1 year during the repair of blast damage.

Major health issues include severe burn treatment and therapy for the victims; permanent hearing loss; long-term tinnitus; vertigo for some exposed to the blast; and post-traumatic stress for victims, first responders, and nearby residents.

**Note:** The National Planning Scenarios core document contains overpressure templates and calculations, as well as tables outlining human injury and property damage criteria for various levels of blast overpressure.
Scenario 13: Biological Attack – Food Contamination

Executive Summary

<table>
<thead>
<tr>
<th>Casualties</th>

<td>Weeks</td>
</tr>
</tbody>
</table>

Scenario General Description:

General Description –
The U.S. food industry has significantly increased its physical and personnel security since 2001. A successful attack could only occur following the illegal acquisition of sensitive information revealing detailed vulnerabilities of a specific production site. However, in this scenario the Universal Adversary (UA) is able to acquire these restricted documents due to a security lapse. The UA uses these sensitive documents and a high degree of careful planning to avoid apprehension and conduct a serious attack on the American people.

Planning Considerations:

Geographical Considerations/Description –
Distribution of the agent is initially at one ground beef facility in a West Coast State. Following retail distribution, the tainted ground beef is in three cities (one on the West Coast, and one each in a southwest and northwest State).

Timeline/Event Dynamics –
- Day minus 30 (D-30): The biological agent is delivered to terrorists (plant workers).
- D-Day: The biological agent is inserted into ground beef at the production facility, and the packages are shipped to affected cities.
- D+2: The first signs of patients with unknown illness appear.
- D+2 – D+12: There is a significant influx of affected individuals into hospitals with 1,200 sick, 300 dead, and 400 hospitalized in the intensive care unit (ICU).
- D+5: Health departments, the Centers for Disease Control and Prevention (CDC), the Food and Drug Administration (FDA), and the United States Department of Agriculture (USDA) begin pursuing epidemiological investigations.
- D+27: A contaminated product trace is made to a ground beef production plant. Decontamination of the plant commences.
- D+33: No new cases of illness are reported.
Mission Areas Activated –

Prevention/Deterrence: Avoiding the attack is contingent on the prevention of infiltration of the beef production system. Deterrence and protection require rapid disease diagnosis, and protective measures to assure food safety.

Emergency Assessment/Diagnosis: Determining cause of illness and tracking the contaminated source is critical.

Emergency Management/Response: Disease outbreaks occur in the three cities containing the tainted beef, which tests coordination of resources. Hospitals and medical staff will be tested, as well as transportation of the ill. Decisions regarding population protective measures will be needed.

Hazard Mitigation: Once disease outbreak occurs, decisions must be made regarding meat production.

Victim Care: Victim care will require diagnosis and treatment of affected population and distribution of prophylaxis for potentially exposed populations.

Investigation/Apprehension: Epidemiology will be critical to trace the source of contamination. Investigation of crime and apprehension of suspects will be needed.

Recovery/Remediation: Contaminated foodstuffs require disposal. The beef plant and sites where anthrax was dispersed may need to be decontaminated.

Key Implications:
The attack results in 500 fatalities, 650 hospitalizations, and 1,800 illnesses. Overall property damage is moderate, and due only to decontamination of affected facilities. However, property and facility disruption (downtime) are significant due to decontamination of affected facilities.

Service disruption is significant in the ground beef industry, and some moderate disruption occurs in other food industries due to the public’s concern about food safety in general.

Although direct financial impact is significant, initial economic impact on the general economy is relatively low. However, the long-term financial impact on the beef marketplace and associated businesses could be significant, and other food industries’ income is likely to be negatively affected by the public’s overall perception of unsafe food. The societal impact of attacks on the food supply generates demands for increased, costly, federally directed food security programs and other measures to reduce the possibility of future attacks. Anthrax may result in fatalities and serious long-term illnesses. Additional cases may arise from frozen beef used after the initial incident.
Scenario 14: Biological Attack –
Foreign Animal Disease (Foot & Mouth Disease)

Executive Summary

<table>
<thead>
<tr>
<th>Casualties</th>
<th>None</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infrastructure Damage</td>
<td>Huge loss of livestock</td>
</tr>
<tr>
<td>Evacuations/Displaced Persons</td>

<tr>
<td>Economic Impact</td>
<td>Hundreds of millions of dollars</td>
</tr>
<tr>
<td>Potential for Multiple Events</td>
<td>Yes</td>
</tr>
<tr>
<td>Recovery Timeline</td>
<td>Months</td>
</tr>
</tbody>
</table>

Although this scenario depicts an intentional attack on the U.S. livestock industry, the accidental importation of certain diseases is also a hazard.

Scenario General Description:

Foot and mouth disease is an acute infectious viral disease that causes blisters, fever, and lameness in cloven-hoofed animals such as cattle and swine. Pregnant animals often abort and dairy cattle may dry up. It spreads rapidly among such animals and can be fatal in young animals. The disease is not considered a human threat.

In this scenario, members of the Universal Adversary (UA) enter the United States to survey large operations in the livestock industries. The UA targets several locations for a coordinated bioterrorism attack on the agricultural industry. Approximately 2 months later, UA teams enter the United States and infect farm animals at specific locations.

Planning Considerations:

Geographical Consideration/Description –

The U.S. livestock transportation system is highly efficient and movements are rapid and frequent. Although the initial event will be localized at transportation facilities in several States, as the biological agent matures and the livestock are transported, the geographical area will widen to include surrounding States where the livestock are delivered.

Timelines/Event Dynamics –

The foreign animal disease (FAD) is initially detected using clinical signs and veterinary medical detection and identification. Over a period of approximately 2 weeks, Federal, State, and local animal health professionals put in place surveillance, detection, containment, remediation, and disposal protocols. This is followed by surveillance, detection, containment, remediation, and disposal protocols continue until testing confirms the FAD is eradicated.
**Mission Areas Activated –**

**Prevention/Deterrence:**
The full force of the agricultural disease protection system will be challenged in order to prevent or detect further attacks.

**Emergency Assessment/Diagnosis:**
Investigations using epidemiological trace-back, microbial forensics, and other approaches will be utilized to determine the source of the agent and identity of the perpetrators.

**Emergency Management/Response:**
If the scope of the outbreak grows, the ability to effectively conduct intrastate and interstate command and control activities, as well as the ability to successfully allocate resources, will be a challenge. States would have a need for containment, Federal funding and personnel, and the use and availability of the National Guard.

**Hazard Mitigation:**
The halt of national movement of susceptible animals may be necessary. Equitable indemnification and when to begin reconstitution of the herds leading to economic recovery will be a major consideration.

**Victim Care:**
It will be necessary to euthanize and dispose of infected and exposed animals. The impact on farmers and farm communities should also be considered.

**Investigation/Apprehension:**
Investigation and apprehension will entail a criminal investigation, involving law enforcement and agricultural experts.

**Recovery/Remediation:**
Ranches, feedlots, transportation modes, and other locations will require decontamination and cleanup. Cleaning and disinfecting are tools used to impede the spread of pathogenic microorganisms. All premises should be cleaned and disinfected under supervision of a regulatory animal health employee.

**Key Implications:**
There are no human fatalities or injuries. However, massive numbers of affected livestock are disposed of because the United States has a national policy not to vaccinate. Property damage will include livestock as well as the equipment, facilities, and land mass required for disposal of euthanized livestock (burial).

All transportation into and out of the affected areas will be severely limited to prevent further dispersion of the FAD to unaffected areas. Both commercial and private/personal travel will be limited.

The extent of economic impact will depend on the ability to limit the geographical spread of the outbreak. A great economic impact will be realized in many sectors of the economy, including but not limited to agriculture. Long-term issues will be centered mostly on foreign trade.

Economic factors will include the value of the affected livestock that must be disposed of; the cost of Federal, State, and local governments to identify, contain, and eradicate the FAD; the cost of disposal and remediation; the loss of revenue suffered by related industries; the loss of revenue suffered by the retail industry due to public perception that the FAD poses a disease risk; the loss of export markets immediately upon confirmation that the FAD exists; and the cost to renew the livestock lost to euthanasia.
The inevitable development and utilization of new technologies to include rapid detection, improved traditional vaccines/advanced molecular vaccines, and new therapeutics (including antiviral agents and other novel biomedical approaches) will lead to a physiological “hardening” of the U.S. farm animal population against FADs, thereby making them unattractive targets of bioterrorism. Although psychological impacts will be realized, human health issues will not be a consideration if a farm animal disease-causing agent is used.
Scenario 15: Cyber Attack

Executive Summary

<table>
<thead>
<tr>
<th>Casualties</th>
<th>None directly</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infrastructure Damage</td>
<td>Cyber</td>
</tr>
<tr>

</tbody>
</table>

Scenario General Description:
In this scenario, the Universal Adversary (UA) conducts cyber attacks that affect several parts of the Nation’s financial infrastructure over the course of several weeks. Specifically, credit-card processing facilities are hacked and numbers are released to the Internet, causing 20 million cards to be cancelled; automated teller machines (ATMs) fail nearly simultaneously across the Nation; major companies report payroll checks are not being received by workers; and several large pension and mutual fund companies have computer malfunctions so severe that they are unable to operate for more than a week.

Planning Considerations:

Geographical Considerations/Description –
The problems are experienced across the Country, as well as internationally. Overseas trade could be affected due to the mistrust in the U.S. Internet infrastructure and the problematic U.S. economy.

Timelines/Event Dynamics –
A year or two is needed for preparation. The attack is executed over a period of months to ensure extended press coverage and undermine confidence in the Internet.

Mission Areas Activated –

Prevention/Deterrence: The strength of private sector companies will be tested in regard to prevention and deterrence.

Infrastructure Protection: Although physical infrastructure is not at great risk, Internet software deteriorates, and numerous systems must be repaired. This requires software expertise, time, and money to correct. If not already impacted, numerous systems would have to shut down.

Emergency Assessment/Diagnosis: The attack will be difficult to recognize. Each attack will end before anyone would have enough time to completely diagnose the problem.

Emergency Management/Response: Emergency response will be split between (1) technically bringing systems back online and instituting business continuity process, and
(2) controlling the public perception of the situation to restore confidence and prevent panicky behaviors.

_Hazard Mitigation:_

All Internet Service Providers (ISPs), Domain Name Service (DNS) operators, and other organizations will need to evaluate their network topologies, diversity, integrity of back-up processes, and other methods of attack prevention. Companies will also have to consider methods to improve the first responder capabilities.

_Victim Care:_

Primarily, victim “care” will be based on economic assurance. Citizens will look for Government assurances that the Internet is a stable and viable method for conducting business and other financial operations.

_Investigation/Apprehension:_

Using intelligence and law enforcement sources and methods, the investigators will need to determine the likely technical source and the identity of the perpetrators.

**Key Implications:**

No significant fatalities or injuries are expected, although collateral effects (e.g., involving hospitals, emergency services responses, and control systems) may have limited fatal consequences. No property damage is expected, although those control systems that are dual-homed may cause physical damage. Service disruption would occur across many sectors with possible loss of confidence in the Internet and services offered such as online banking and e-commerce. The greatest impact will be intermittent and unpredictable disruptions to the Internet, which will affect online banking, other e-commerce services, and general public confidence.
APPENDIX: Scenario Working Group Members

The Homeland Security Council receives interagency guidance via a number of Policy Coordinating Committees (PCCs). One of them is the Domestic Threat, Response, and Incident Management (DTRIM) PCC; the Scenarios Working Group (SWG) supports the DTRIM. The members of the SWG are as follows:

CHAIR: Janet K. Benini, Director of Response and Planning, White House Homeland Security Council
